

ASEN 2003 LAB 1: ROLLER COASTER DESIGN

- Assigned: Wednesday, January 16, 2019 (or Thursday, January 17)
- Group Report Due: Monday, January 28, 2019, end of lab period (or Tuesday, January 29)

OBJECTIVES

- Use your knowledge of particle dynamics to design and analyze the performance of a new roller coaster.
- Gain design experience using an example in particle dynamics.
- Practice using FBD's and energy methods to set up and solve problems in dynamics.
- Document your design and analysis in a professional technical report.

PROBLEM STATEMENT

Roller coasters are one of the main attractions for amusement and theme parks and vary considerably in their design. Trains on the coaster are brought to the top of a hill by some kind of lifting mechanism and from then on they coast for the remainder of the ride. Although things like friction, air resistance, mass distribution in the cars, etc. complicate things, we will do a first-cut design of a roller coaster by ignoring all that and treating the train as a point mass moving on a frictionless rail through space.

The primary tasks for this design project are to:

- 1) analyze the dynamics of typical coaster track elements (hills, valleys, turns, loops, twists);
- 2) design specific track elements meeting the project requirements;
- 3) assemble a track design;
- 4) analyze overall track performance; and
- 5) document the design and analysis in a group lab report.

The features that make a roller coaster ride exciting are novelty, speed, and G's experienced, so your task is to optimize the experience in terms of these parameters. We will quantify novelty in terms of the number of different elements incorporated in the design. Maximum speed is limited by the initial height of the coaster, and you can adjust the speed entering and leaving each element of the track by selecting its height. G's experienced must be defined carefully. The number of G's the particle experiences is equal to the normal force (N) exerted by the track on it, divided by the particle weight (mg). The normal force will also be a function of m , so the mass of the car should not affect the final "G" calculation. Note that the normal force is a vector quantity so we can express the number of G's felt in each of three directions relative to the train car (up, forward, left for example). The human body is more sensitive to G's in some directions than others, so we will set the design requirements to make the ride comfortable (well, at least not deadly) for the riders.

ASSUMPTIONS

1. Assume that the roller coaster train and people inside may be treated as a particle or point mass.
2. The track is frictionless (except for any braking sections).
3. The train is initially brought to the top of a 125 m (h_0) hill where it has zero velocity. The speed at any point on the track can be found based on the height compared to the initial height. $v(h) = \sqrt{2g(h_0 - h)}$.
4. The train must remain above ground (i.e. the height must always be greater than or equal to zero).

5. The train is locked to the track so that the force exerted on the train by the track can act in any direction orthogonal to the track (i.e. you can be held in your seat by the lap bar and pushed right or left by the side of the seat).
6. A *track element* will refer to one of the following: ramp, circular or parabolic hill, circular or parabolic valley, loop, or helix. If you think of other ideas for elements please discuss with the instructor. In addition to track elements the design must include a banked turn and a braking section.

DESIGN REQUIREMENTS

1. The total linear distance of the track must be less than 1200 m with the train coming to rest (using a braking mechanism) at a final height of 0 m.
2. The coaster must include at least three different types of track elements with transitions between them.
3. All transitions must be smooth.
4. The coaster must include at least one section that produces zero g throughout the ENTIRE element (not just at one point).
5. The coaster track must contain at least one banked turn at a constant or changing altitude (i.e. the track cannot remain in a single plane.)
6. The G's experienced by the passengers must be within the following ranges defined in a coordinate system fixed to the train:
 - forward (back of seat pushing on rider) $< 5\text{ G}$
 - back (seat restraint pushing back the rider) $< 4\text{ G}$
 - up (i.e. pushing up through the rider's seat) $< 6\text{ G}$
 - down (i.e. pushing down on the rider through the lap bar) $< 1\text{ G}$
 - lateral (pushing to the left or right on the rider) $< 3\text{ G}$

HINTS & WARM UP EXERCISES

1. To compute the "Gs" acting on a passenger in a certain direction, take the total force exerted on the passenger in that direction and divide by " $m\text{ g}$ ", where g is the gravitational acceleration (9.81 m/s^2).
Examples:
 - a. The upward G's experienced by someone standing on the floor is the normal force of the floor on their feet ($N = mg$) divided by their weight (mg), and equals $N / m\text{ g} = 1\text{ G}$.
 - b. The backwards G's experienced by a passenger in a train car that is decelerating at a rate 20 m/s^2 equals the force acting on them in that direction, $F = m * 20$, divided by their weight, $m\text{ g}$, and equals $20/g \sim 2\text{ Gs}$.
2. Draw FBD and mass-acceleration diagrams for each type of track element.
Derive the g forces acting on the passenger in each direction for each of these elements.
(We will discuss these in lab sections the week of 1/21/19 – come prepared with your work & questions.)

REPORT CONTENTS

Title Page - Lab# and Title, Course Number, Student Names, Date Submitted

Abstract - Briefly summarize the rest of the report including the objectives of the lab, what was actually done, the most important qualitative and quantitative results, and your conclusions. The abstract should be less than 200 words.

Introduction

- Provide an overview of the project objectives, design requirements and assumptions.
- Sketch or map your overall track design and give a qualitative description of features. Describe your design process.

Design (should have accompanying diagrams, can be handwritten)

- For each unique track element and transition region provide a qualitative description, a clear mathematical specification, and a sketch.
- Show a FBD and acceleration diagram for all critical points. **These diagrams can be side by side, but must be distinct, i.e. do not put them together.**
- Show the equations used to select characteristics of the section.
- Give expressions for the acceleration and G loading of the train throughout the track section.

Performance Analysis

- Plot the up/down, forward/backward, and lateral G loads as a function of position s along the track. Please make sure to identify the sections on your figure.
- Plot the train speed as a function of position along the track.
- Describe the overall performance of your coaster. Discuss any remaining problems in the design. Would your design be safe and practical to actually build and run?
- Extra Credit – What is the duration of your ride?

Conclusions and Recommendations – Summarize your design experience. What was learned from the design? Did you meet the requirements? What possible improvements could be made to your design and to the assignment?

References - List reference material used in professional format. Each reference must be cited in the text.

Acknowledgements - Describe assistance or contributions provided by classmates or others (not including group members who authored the report).

Appendix A – Insert the team-member contributions table.

Appendix B - Include well-commented computer code used for the design and to generate plots.

REPORT GRADING

	Title Page
5	Abstract
	Table of Contents
10	Introduction
40	Design: FBD's, equations, description, software (see below)
20	Performance (10 pts for plots, 10 pts for discussion)
5	Conclusions and Recommendations
5	References & Acknowledgments
15	(Style and Clarity - includes title page, ToC, organization, grammar, spelling)
100	

Deductions

One point will be deducted for each missing unit or label on plot axes (up to 10 points).

TAs will have discretion to deduct up to 5 points for using font sizes in your plots that are too small.

It is not enough to write MATLAB code that gives you the right answer. Your code should be easy to follow and use structured programming methods. To encourage such coding, a MATLAB style score will be included in the design score. To receive the highest score, you will need the following:

- Each piece of code should have the input and output clearly defined, with units.
- Use self-documenting variable names (but don't go crazy. V is fine. You do not have to call the variable Velocity).
- Complicated and detailed calculations should go in functions, especially if you need to run the same calculation on multiple inputs.
- Name(s) of the programmers should be at the top of the code.
- A short purpose for each piece of code should be provided (one sentence is sufficient).
- Some comments are required (not a huge amount – but enough that the reader can see what you were up to).
